"On the topology the representation variety of a punctured surface group in $PSL(2,\mathbb{R})$ "

Prof. Dr. Gabriele Mondello, Università di Roma, Italien

Abstract: Goldman classified the connected components of the representation variety of a closed surface group in $PSL(2,\mathbb{R})$ and Hitchin described the topology of the components with nonzero Euler number.

In this talk I will describe how to perform a similar analysis for surfaces with punctures, thus detecting the topology of the representation variety in $PSL(2,\mathbb{R})$ with assigned peripheral monodromy and nonzero Euler number.

We follow Hitchin's strategy and we exploit Simpson's correspondence between representations of punctured surface groups and parabolic Higgs bundles
